Children up to 40 kg
Marcaine Spinal Heavy may be used in children.
One of the differences between small children and adults is a relatively high CSF volume in infants and neonates, requiring a relatively larger dose/kg to produce the same level of block as compared to adults.

Contraindications
Hypersensitivity to local anaesthetics of the amide type, or to any of the excipients.
General contraindications related to intrathecal anaesthesia should be taken into account:
- Acute active disease of the central nervous system, such as meningitis, tumours, poliomyelitis and cranial haemorrhage.
- Spinal stenosis and active disease (eg, spondylitis, tumour) or recent trauma (eg, fracture) in the vertebral column.
- Septicaemia.
- Pernicious anaemia with subacute combined degeneration of the Spinal cord.
- Pyogenic infection of the skin at or adjacent to the site of puncture.
- Cardiogenic or hypovolaemic shock.
- Coagulation disorders or ongoing anticoagulant treatment.

Special warnings and precautions for use
Intrathecal anaesthesia should only be undertaken by or under the supervision of clinicians with the necessary knowledge and experience.
Regional anaesthetic procedures should always be performed in a properly equipped and staffed area with equipment and drugs necessary for monitoring and emergency resuscitation immediately available.
Intravenous access, e.g. an i.v. infusion, should be in place before starting the intrathecal anaesthesia. Clinicians should have received adequate and appropriate training in the procedure to be performed and should be familiar with the diagnosis and treatment of side effects, systemic toxicity or other complications (see Overdose).

Patients in poor general condition due to ageing or other compromising factors such as partial or complete heart conduction block, advanced liver or renal dysfunction require special attention although regional anaesthesia may be the optimal choice for surgery in these patients. Patients treated with anti-arrhythmic drugs class III (eg, amiodarone) should be under close surveillance and ECG monitoring considered, since cardiac effects may be additive (See Interaction).

Like all local anaesthetic drugs, bupivacaine may cause acute toxicity effects on the central nervous and cardiovascular systems, if utilised for local anaesthetic procedures resulting in high blood concentrations of the drug. This is especially the case after unintentional intravascular administration. Ventricular arrhythmia, ventricular fibrillation, sudden cardiovascular collapse and death have been reported in connection with high systemic concentrations of bupivacaine. However, high systemic concentrations are not expected with doses normally used for intrathecal anaesthesia.

A rare, though severe, adverse reaction following Spinal anaesthesia is high or total Spinal blockade resulting in cardiovascular and respiratory depression. The cardiovascular depression is caused by extensive sympathetic blockade which may result in profound hypotension and bradycardia, or even cardiac arrest. Respiratory depression may be caused by blockade of the innervation of the respiratory muscles, including the diaphragm.

There is an increased risk for high or total Spinal blockade in the elderly and in patients in the late stages of pregnancy. The dose should therefore be reduced in these patients (see also Posology and method of administration).

Patients with hypovolaemia can develop sudden and severe hypotension during intrathecal anaesthesia, regardless of the local anaesthetic used. The hypotension usually seen after intrathecal blocks in adults is uncommon in children under the age of 8. Neurological injury is a rare consequence of intrathecal anaesthesia and may result in paraesthesia, anaesthesia, motor weakness and paralysis. Occasionally these are permanent.

Neurological disorders, such as multiple sclerosis, haemiplegia, paraplegia and neuromuscular disorders are not thought to be adversely affected by intrathecal anaesthesia, but call for caution. Before treatment is instituted, consideration should be taken if the benefits outweigh the possible risks for the patient.

**Interactions**

Bupivacaine should be used with caution in patients receiving other local anaesthetics or agents structurally related to amide-type local anaesthetics eg, certain anti-arrhythmics, such as lidocaine and mexiletine, since the systemic toxic effects are additive. Specific interaction studies with bupivacaine and anti-arrhythmic drugs class III (eg, amiodarone) have not been performed, but caution should be advised (see also Special warnings and special precautions for use).

**Pregnancy and lactation**

**Pregnancy**

It is reasonable to assume that a large number of pregnant women and women of child-bearing age have been given bupivacaine. No specific disturbances to the reproductive process have so far been reported, e.g. no increased incidence of malformations (see Pharmacokinetic properties). It should be noted that the dose should be reduced in patients in the late stages of pregnancy (See also Posology and method of administration).

**Lactation**

Bupivacaine enters the mother’s milk, but in such small amounts that there is generally no risk of this affecting the neonate.

**Effects on ability to drive and use machines**

Besides the direct anaesthetic effect, local anaesthetics may have a very mild effect on mental function and coordination even in the absence of overt CNS toxicity and may temporarily impair locomotion and alertness.
Undesirable effects
The adverse reaction profile for Marcaine Spinal is similar to those for other long acting local anaesthetics administered intrathecally. Adverse reactions caused by the drug per se are difficult to distinguish from the physiological effects of the nerve block (eg, decrease in blood pressure, bradycardia, temporary urinary retention), events caused directly (eg, Spinal haematomata) or indirectly (eg, meningitis, epidural abscess) by the needle puncture or events associated to cerebrospinal leakage (eg, postdural puncture headache).

Overdose
Acute systemic toxicity
Marcaine Spinal used as recommended is not likely to cause blood levels high enough to cause systemic toxicity. However, if other local anaesthetics are concomitantly administered, toxic effects are additive and may cause systemic toxic reactions.

Treatment of acute systemic toxicity
If signs of acute systemic toxicity or total Spinal block appear, injection of the local anaesthetic should be stopped immediately and cardiovascular and neurological symptoms (convulsions, CNS depression) must be treated adequately.

If circulatory arrest should occur, immediate cardiopulmonary resuscitation should be instituted. Optimal oxygenation and ventilation and circulatory support as well as treatment of acidosis are of vital importance.

If cardiovascular depression is evident (hypotension, bradycardia), ephedrine 5-10 mg iv should be given and this dose should be repeated, if necessary, after 2-3 minutes. Children should be given ephedrine doses commensurate with their age and weight.

If convulsions due to systemic toxicity occurs, the objective of treatment is to maintain oxygenation, stop the convulsions and support the circulation. Oxygen must be given and ventilation assisted, when necessary (mask and bag or tracheal intubation). An anticonvulsant should be given iv if the convulsions do not stop spontaneously in 15-20 seconds. Thiopentone sodium 1-3 mg/kg iv will abort the convulsions rapidly. Alternatively diazepam 0.1 mg/kg iv may be used, although its action will be slow. Prolonged convulsions may jeopardize the patient’s ventilation and oxygenation. If so, injection of a muscle relaxant (eg, succinylcholine 1 mg/kg) will rapidly stop the convulsions so that ventilation and oxygenation can be controlled. Endotracheal intubation must be considered in such situations.

Pharmacodynamic properties
Pharmacotherapeutic group (ATC code): N01B B01
Bupivacaine is a local anaesthetic of the amide type. Given as an intrathecal anaesthetic it has a rapid onset and a medium to long duration. The duration is dose-dependent.

Bupivacaine, like other local anaesthetics, causes a reversible blockade of impulse propagation along nerve fibres by preventing the inward movement of sodium ions through the nerve membrane.

Marcaine Spinal Heavy is hyperbaric and its initial spread in the intrathecal space is affected by gravity. Due to the small dose the intrathecal distribution results in a relatively low concentration and the duration of the local anaesthetic tends to be relatively short.

Plain solutions (without dextrose) produce a less predictable level of block, but of longer duration, than the hyperbaric solutions.

Pharmacokinetic properties
Bupivacaine has a pKa of 8.2 and a partition coefficient of 346 (25°C n-octanol/ phosphate buffer pH 7.4).
Preclinical safety data
Based on conventional studies with bupivacaine of safety pharmacology, single and repeated dose toxicity, reproduction toxicity, mutagenic potential and local toxicity, no hazards for humans were identified other than those which can be expected on the basis of the pharmacodynamic action of high doses of bupivacaine (eg, CNS signs and cardiotoxicity.)

List of excipients
- Dextrose monohydrate, 80.0 mg
- Sodium hydroxide and/or hydrochloric acid for pH adjustment to 4.0-6.0
- Water for injections to 1 mL

The relative density of the solution is 1.026 at 20°C (corresponding to 1.021 at 37°C).

Incompatibilities
Additions to Spinal solutions are not generally recommended.

Shelf-life
Please see outer pack.

Special precautions for storage
Do not store above 25°C. Do not freeze.

Pack size
Please see outer pack.

Nature and contents of container
Marcaine Spinal Heavy is supplied in type I glass ampoules with/without blister.

Instructions for use/handling
Marcaine Spinal Heavy is free from preservative and intended for single use only. Any remaining solution should be discarded.

Since Marcaine Spinal Heavy contains glucose, caramelization may occur during autoclaving. This preparation should therefore not be re-sterilized.
