INDERAL 10 mg, 40 mg, 80 mg Tablet
ASTRAZENECA

Presentation
Tablets containing 10 mg, 40 mg or 80 mg Propranolol Hydrochloride Ph. Eur.
Injection for intravenous use containing Propranolol Hydrochloride Ph. Eur. 1 mg per 1 ml, presented in glass ampoules of 1 ml.

Indications
I) Control of hypertension
II) Management of angina pectoris
III) Long term prophylaxis after recovery from acute myocardial infarction
IV) Control of cardiac arrhythmias
V) Prophylaxis of migraine
VI) Management of essential tremor
VII) Control of anxiety and anxiety tachycardia
VIII) Adjunctive management of thyrotoxicosis and thyrotoxic crisis
IX) Management of hypertrophic obstructive cardiomyopathy
X) Management of phaeochromocytoma (‘Inderal’ should only be started in the presence of effective alpha blockade)

Dosage and administration
Since the half-life may be increased in patients with significant hepatic or renal impairment, caution must be exercised when starting treatment and selecting the initial dose.

Oral Dosage
Adults
Hypertension: A starting dose of 80 mg twice a day may be increased at weekly intervals according to response. The usual dose range is 160-320 mg per day and the maximum daily dose must not exceed 640 mg per day (see summary table below). With concurrent diuretic or other antihypertensive drugs a further reduction of blood pressure is obtained.

Angina, anxiety, migraine and essential tremor: A starting dose of 40 mg two or three times daily may be increased by the same amount at weekly intervals according to patient response. An adequate

Response in anxiety, migraine and essential tremor is usually seen in the range 80-160 mg/day, and in angina in the range 120-240 mg/day. A maximum daily dose of 240 mg for migraine and 480 mg for angina must not be exceeded (see summary table).

Arrhythmias, anxiety tachycardia, hypertrophic obstructive cardiomyopathy and thyrotoxicosis: A dosage range of 10-40 mg three or four times a day usually achieves the required response. A maximum daily dose of 240 mg for arrhythmias must not be exceeded (see summary table).

Post-myocardial infarction: Treatment should start between days 5 and 21 after myocardial infarction, with an initial dose of 40 mg four times a day for 2 or 3 days. In order to improve compliance the total daily dosage may thereafter be given as 80 mg twice a day (see summary table).

Phaeochromocytoma: (‘Inderal’ is to be used only in the presence of effective alpha-blockade). Preoperative: 60 mg daily for three days is recommended. Non-operable malignant cases: 30 mg daily (see summary table).

| Summary Table of Inderal Oral Dosage - Adults (in divided daily doses) |
|-------------------------------------------------|-----------------|-----------------|
| Hypertension                                   | 160 mg          | 640 mg          |
| Angina pectoris                                | 80 mg           | 480 mg          |
| Arrhythmias                                    | 30 mg           | 240 mg          |
| Migraine                                       | 80 mg           | 240 mg          |
| Tremor                                         | 40 mg           | 160 mg          |
| Anxiety                                        | 80 mg           | 160 mg          |
| Anxiety Tachycardia                            | 30 mg           | 160 mg          |
| Thyrotoxicosis                                 | 30 mg           | 160 mg          |
| Cardiomyopathy                                 | 30 mg           | 160 mg          |
| Phaeochromocytoma                              | 60 mg (pre op)  | 60 mg           |
|                                                | 30 mg (maintenance) | 30 mg       |
| Post-infarction                                | 160 mg          | 160 mg          |

Elderly
Evidence concerning the relation between blood level and age is conflicting. With regard to the elderly, the optimum dose should be individually determined according to clinical response.
Contra-indications

‘Inderal’ must not be used if there is a history of bronchial asthma or bronchospasm. Bronchospasm can usually be reversed by beta2-agonist bronchodilators such as salbutamol. Large doses of the beta2-agonist bronchodilator may be required to overcome the beta-blockade produced by propranolol and the dose should be titrated according to the clinical response; both intravenous and inhalational administration should be considered. The use of intravenous aminophylline and/or the use of ipratropium, (given by nebuliser), may also be considered. Glucagon (1 to 2 mg given intravenously) has also been reported to produce a bronchodilator effect in asthmatic patients. Oxygen or artificial ventilation may be required in severe cases. ‘Inderal’ as with other beta-blockers must not be used in patients with any of the following: known hypersensitivity to the substance; bradycardia; cardiogenic shock; hypotension; metabolic acidosis; after prolonged fasting; severe peripheral arterial circulatory disturbances; second or third degree heart block; sick sinus syndrome; untreated (with an alpha adrenoceptor antagonist) phaeochromocytoma; uncontrolled heart failure; Prinzmetal’s angina.

‘Inderal’ must not be used in patients prone to hypoglycaemia, i.e., patients after prolonged fasting or patients with restricted counter-regulatory reserves. Patients with restricted-counter regulatory reserves may have reduced autonomic and hormonal responses to hypoglycaemia which includes glycogenolysis, gluconeogenesis and/or impaired modulation of insulin secretion. Patients at risk for an inadequate response to hypoglycaemia includes individuals with malnutrition, prolonged fasting, starvation, chronic liver disease, diabetes and concomitant use of drugs which block the full response to catecholamines.

Children

Dosage should be individually determined and the following is only a guide:

Arrhythmias, phaeochromocytoma, thyrotoxicosis:
Oral: 0.25 - 0.5 mg/kg three or four times daily as required.

Migraine: Oral: Under the age of 12:20 mg two or three times daily. Over the age of 12: the adult dose

Intravenous Dosage

The intravenous injection is intended for the emergency treatment of cardiac arrhythmias and thyrotoxic crisis only.

Adults

The initial dose is 1 mg (1 ml) injected over one minute. This may be repeated at two minute intervals until a response is observed, or to a maximum dose of 10 mg in conscious patients or 5 mg in patients under anaesthesia.

Warnings and precautions

‘Inderal’ as with other beta-blockers:

- may block/modify the signs and symptoms of hypoglycaemia (especially tachycardia). Inderal’ occasionally causes hypoglycaemia, even in non-diabetic patients, e.g., neonates, infants, children, elderly patients, patients on haemodialysis or patients suffering from chronic liver disease and patients suffering from overdose. Severe hypoglycaemia associated with ‘Inderal’ has rarely presented with seizures and/or coma in isolated patients. Caution must be exercised in the concurrent use of ‘Inderal’ and hypoglycaemic therapy in diabetic patients. ‘Inderal’ may prolong the hypoglycaemic response to insulin.
- may mask the signs of thyrotoxicosis.
- will reduce heart rate, as a result of its pharmacological action. In the rare instances when a treated patient develops symptoms which may be attributable to a slow heart rate, the dose may be reduced.
- should not be discontinued abruptly in patients suffering from ischaemic heart disease. Either the equivalent dosage of another beta-blocker may be substituted or the withdrawal of ‘Inderal’ should be gradual.
- may cause a more severe reaction to a variety of allergens, when given to patients with a history of anaphylactic reaction to such allergens. Such patients may be unresponsive to the usual doses of adrenalin used to treat the allergic reactions.

‘Inderal’ must be used with caution in patients with decompensated cirrhosis.

In patients with significant hepatic or renal impairment care should be taken when starting treatment and selecting the initial dose.

In patients with portal hypertension, liver function may deteriorate and hepatic encephalopathy may develop. There have been reports suggesting that treatment with propranolol may increase the risk of developing hepatic encephalopathy.

**Interactions with other medicaments and other forms of interaction**

‘Inderal’ modifies the tachycardia of hypoglycaemia. Caution must be exercised in the concurrent use of ‘Inderal’ and hypoglycaemic therapy in diabetic patients. ‘Inderal’ may prolong the hypoglycaemic response to insulin (see Contraindications, Warnings and Precautions).

Caution must be exercised in prescribing a beta-blocker with Class I antiarrhythmic agents such as disopyramide.

Digitalis glycosides in association with beta-blockers may increase atrioventricular conduction time. Combined use of beta-blockers and calcium channel blockers with negative inotropic effects (e.g. verapamil, diltiazem) can lead to an exaggeration of these effects particularly in patients with impaired ventricular function and/or SA or AV conduction abnormalities. This may result in severe hypotension, bradycardia and cardiac failure. Neither the beta-blocker nor the calcium channel blocker should be administered intravenously within 48 hours of discontinuing the other.

Concomitant therapy with dihydropyridine calcium channel blockers, e.g. nifedipine, may increase the risk of hypotension and cardiac failure may occur in patients with latent cardiac insufficiency.

Concomitant use of sympathomimetic agents, e.g. adrenalin, may counteract the effect of beta-blockers. Caution must be exercised in the parenteral administration of preparations containing adrenalin to patients taking beta-blockers as, in rare cases, vasoconstriction, hypertension and bradycardia may result.

Administration of ‘Inderal’ during infusion of lignocaine may increase the plasma concentration of lignocaine by approximately 30%. Patients already receiving ‘Inderal’ tend to have higher lignocaine levels than controls. The combination should be avoided.

Concomitant use of cimetidine or hydralazine increases, whereas concomitant use of alcohol decreases, the plasma levels of propranolol.

Beta-blockers may exacerbate the rebound hypertension which can follow the withdrawal of clonidine. If the two drugs are co-administered, the beta-blocker should be withdrawn several days before discontinuing clonidine. If replacing clonidine by beta-blocker therapy, the introduction of beta-blockers should be delayed for several days after clonidine administration has stopped.

Caution must be exercised if ergotamine, dihydroergotamine or related compounds are given in combination with ‘Inderal’ since vasospastic reactions have been reported in a few patients.

Concomitant use of prostaglandin synthetase inhibiting drugs, e.g. ibuprofen and indomethacin, may decrease the hypotensive effects of ‘Inderal’.

Concomitant administration of ‘Inderal’ and chlorpromazine may result in an increase in plasma levels of both drugs. This may lead to an enhanced antipsychotic effect for chlorpromazine and an increased antihypertensive effect for ‘Inderal’.
Caution must be exercised when using anaesthetic agents with ‘Inderal’. The anaesthetist should be informed and the choice of anaesthetic should be an agent with as little negative inotropic activity as possible. Use of beta-blockers with anaesthetic drugs may result in attenuation of the reflex tachycardia and increase the risk of hypotension. Anaesthetic agents causing myocardial depression are best avoided.

Pharmacokinetic studies have shown that the following agents may interact with propranolol due to effects on enzyme systems in the liver which metabolise propranolol and these agents: quinidine, propafenone, rifampicin, theophylline, warfarin, thioridazine and dihydropyridine calcium channel blockers such as nifedipine, nisoldipine, nicardipine, isradipine and lacidipine. Owing to the fact that blood concentrations of either agent may be affected dosage adjustments may be needed according to clinical judgement. (See also the Interaction above concerning the concomitant therapy with dihydropyridine calcium channel blockers).

Possible adverse reactions
‘Inderal’ is usually well tolerated. In clinical studies the possible adverse reactions reported are usually attributable to the pharmacological actions of propranolol.

The following possible adverse reactions, listed by body system, have been reported.

**Cardiovascular:** bradycardia; heart failure deterioration; postural hypotension which may be associated with syncope; cold extremities. In susceptible patients: precipitation of heart block; exacerbation of intermittent claudication; Raynaud’s phenomenon.

**CNS:** confusion; dizziness; mood changes; nightmares; psychoses and hallucinations; sleep disturbances.

**Endocrine:** Hypoglycaemia in neonates, infants, children, elderly patients, patients on hemodialysis, patients on concomitant antidiabetic therapy, patients with prolonged fasting and patients with chronic liver disease has been reported (see Contraindications, Warnings and Precautions and Interactions)

**Gastrointestinal:** gastrointestinal disturbance.

**Haematological:** purpura; thrombocytopenia.

**Integumentary:** alopecia; dry eyes; psoriasiform skin reactions; exacerbation of psoriasis; skin rashes.

**Neurological:** paraesthesia.

**Respiratory:** bronchospasm may occur in patients with bronchial asthma or a history of asthmatic complaints, sometimes with fatal outcome (see Contraindications).

**Special senses:** visual disturbances.

Others: fatigue and/or lassitude (often transient); an increase in ANA (Antinuclear Antibodies) has been observed, however the clinical relevance of this is not clear; isolated reports of myasthenia gravis like syndrome or exacerbation of myasthenia gravis have been reported.

Discontinuance of the drug should be considered if, according to clinical judgement, the well-being of the patient is adversely affected by any of the above reactions. Cessation of therapy with a beta-blocker should be gradual. In the rare event of intolerance, manifested as bradycardia and hypotension, the

### Pregnancy and lactation

**Pregnancy**
As with all drugs ‘Inderal’ should not be given during pregnancy unless its use is essential. There is no evidence of teratogenicity with ‘Inderal’. However beta-blockers reduce placental perfusion, which may result in intra-uterine foetal death, immature and premature deliveries. In addition, adverse effects (especially hypoglycaemia and bradycardia in the neonate and bradycardia in the foetus) may occur. There is an increased risk of cardiac and pulmonary complications in the neonate in the post-natal period.

**Lactation**
Most beta-blockers, particularly lipophilic compounds, will pass into breast milk although to a variable extent. Breast-feeding is therefore not recommended following administration of these compounds.

### Effect on ability to drive or operate machinery
Use is unlikely to result in any impairment of the ability of patients to drive or operate machinery. However it should be taken into account that occasionally dizziness or fatigue may occur.
Propranolol is a racemic mixture and the active form is the S(-) isomer, of propranolol. With the exception of inhibition of the conversion of thyroxine to triiodothyronine it is unlikely that any additional ancillary properties possessed by R(+) propranolol, in comparison with the racemic mixture will give rise to different therapeutic effects.

Propranolol is effective and well-tolerated in most ethnic populations, although the response may be less in black patients.

**Pharmacokinetic Properties**
Following intravenous administration the plasma half-life of propranolol is about 2 hours and the ratio of metabolites to parent drug in the blood is lower than after oral administration. In particular 4-hydroxypropranolol is not present after intravenous administration. Propranolol is completely absorbed after oral administration and peak plasma concentrations occur 1-2 hours after dosing in fasting patients. The liver removes up to 90% of an oral dose with an elimination half-life of 3 to 6 hours. Propranolol is widely and rapidly distributed throughout the body with highest levels occurring in the lungs, liver, kidney, brain and heart. Propranolol is highly protein bound (80-95%).

**Pharmaceutical Particulars**
**Compatibility With Intravenous Infusion Fluids**
‘Inderal’ injection is compatible with 0.9% w/v sodium chloride and 5% w/v dextrose.

**Storage**
‘Inderal’ tablets: do not store above 30°C. Protect from light and moisture.
‘Inderal’ injection: do not store above 30°C. Protect from light.

**Shelf Life**
‘Inderal’ tablets: Please refer to expiry date on the blister strip or outer carton.
‘Inderal’ injection: Please refer to expiry date on the label or outer carton.

**Pack size**
Please refer to the outer carton for pack size.

drug should be withdrawn and, if necessary, treatment for overdosage instituted.

**Overdosage**
The symptoms of overdosage may include bradycardia, hypotension, acute cardiac insufficiency and bronchospasm.

General treatment should include: close supervision, treatment in an intensive care ward, the use of gastric lavage, activated charcoal and a laxative to prevent absorption of any drug still present in the gastrointestinal tract, the use of plasma or plasma substitutes to treat hypotension and shock.

Excessive bradycardia can be countered with atropine 1-2 mg intravenously and/or a cardiac pacemaker. If necessary, this may be followed by a bolus dose of glucagon 10 mg intravenously. If required, this may be repeated or followed by an intravenous infusion of glucagon 1-10 mg/hour depending on response. If no response to glucagon occurs or if glucagon is unavailable, a beta-adrenoceptor stimulant such as dobutamine 2.5 to 10 micrograms/kg/minute by intravenous infusion may be given. Dobutamine, because of its positive inotropic effect could also be used to treat hypotension and acute cardiac insufficiency. It is likely that these doses would be inadequate to reverse the cardiac effects of beta-blockade if a large overdose has been taken. The dose of dobutamine should therefore be increased if necessary to achieve the required response according to the clinical condition of the patient.

**Pharmacological properties**
**Pharmacodynamic properties**
Propranolol is a competitive antagonist at both the beta1- and beta2- adrenoceptors. It has no agonist activity at the beta-adrenoceptor, but has membrane stablising activity at concentrations exceeding 1-3 mg/litre, though such concentrations are rarely achieved during oral therapy. Competitive beta-adrenoceptor blockade has been demonstrated in man by a parallel shift to the right in the dose-heart rate response curve to beta agonists such as isoprenaline. Propranolol, as with other beta-blockers, has negative inotropic effects, and is therefore contraindicated in uncontrolled heart failure (See Warnings/Precautions).
